Travail en collaboration avec Claire Launay (Albert Einstein College of Medicine, New-York) et Bruno Galerne (Université d’Orléans).
Determinantal Point Processes (DPP) provide a family of models of random configurations that favor **diversity** or **repulsion** between points:

![Realization of a DPP](image1)
![Realization of a Bernoulli process](image2)

(a) Realization of a DPP  
(b) Realization of a Bernoulli process

**On continuous domains**: Introduced by Macchi (1975) for modeling fermions, regain of interest in spatial statistics (Lavancier, Møller, Rubak, 2015).
Determinantal Point Processes

- On discrete domains: Various applications in machine learning based on selection of diverse subsets:
  - Recommendation systems (Wilhelm et al., 2018).
  - Text summarization (Kulesza, Taskar, 2012; Dupuy, Bach, 2017).
  - Feature selection (Belhadji, Bardenet, Chainais, 2018).
  - ...

- Advantages of (discrete) DPPs (compared to Gibbs processes):
  - Similarity between points encoded in a matrix $K$ called kernel
  - Moments and marginal probabilities have closed form formulas
  - Exact simulation algorithm

I went to this place two weeks ago with my aunt and my cousins. It was a lovely sunny afternoon. We had a chocolate cake and drank an apricot juice. The employees were charming and really helpful. We stayed there the whole afternoon, laughing, playing and enjoying the nice weather. Thanks again! I definitely recommend it!
Discrete determinantal point processes

In this talk we work on a discrete set made of $N$ elements that we identify with $\mathcal{Y} = \{1, \ldots, N\}$.

Definition

Let $K$ be a Hermitian matrix of size $N \times N$ such that

$$0 \preceq K \preceq I.$$

The random subset $Y \subset \mathcal{Y}$ defined by the inclusion probabilities

$$\forall A \subset \mathcal{Y}, \quad \mathbb{P}(A \subset Y) = \det(K_A)$$

is determinantal point process of kernel $K$.

One writes $Y \sim \text{DPP}(K)$.
Properties of DPP

- The diagonal coefficients $K_{ii}$ define the inclusion probability of each element $i$:
  \[ \mathbb{P}(i \in Y) = K_{ii}. \]

- The off-diagonal coefficients $K_{ij}$ give the repulsion between points $i$ and $j$:
  \[ \mathbb{P}\{i, j\} \subset Y = \mathbb{P}(i \in Y) \mathbb{P}(j \in Y) - |K_{ij}|^2. \]

- A DPP is repulsive since $\mathbb{P}\{i, j\} \subset Y$ is always smaller than in the case of independent point selection (Bernoulli process).

- By construction, DPPs are simple random sets.

Let $\{\lambda_1, \ldots, \lambda_N\} \in \mathbb{R}$ be the eigenvalues of $K$. 
Properties of DPP

- The diagonal coefficients $K_{ii}$ define the inclusion probability of each element $i$:
  \[ P(i \in Y) = K_{ii}. \]

- The off-diagonal coefficients $K_{ij}$ gives the repulsion between the points $i$ and $j$:
  \[ P(\{i,j\} \subset Y) = P(i \in Y)P(j \in Y) - |K_{ij}|^2. \]

- A DPP is repulsive since $P(\{i,j\} \subset Y)$ is always smaller than in the case of independent point selection (Bernoulli process).

- By construction, DPPs are simple random sets.

Let $\{\lambda_1, \ldots, \lambda_N\} \in \mathbb{R}$ be the eigenvalues of $K$. 
Properties of DPP

**Cardinality:** it satisfies $|Y| \sim \sum_{i \in Y} \text{Ber}(\lambda_i)$ (sum of independent Bernoulli random variables of parameter $\lambda_i$). Hence

$$
\mathbb{E}(|Y|) = \sum_{i \in Y} \lambda_i = \text{Tr}(K) = \sum_{i \in Y} K_{ii}
$$

$$
\text{Var}(|Y|) = \sum_{i \in Y} \lambda_i (1 - \lambda_i)
$$
Properties of DPP

**Cardinality**: it satisfies $|Y| \sim \sum_{i \in \mathcal{Y}} \text{Ber}(\lambda_i)$

(sum of independent Bernoulli random variables of parameter $\lambda_i$). Hence

$$
\mathbb{E}(|Y|) = \sum_{i \in \mathcal{Y}} \lambda_i = \text{Tr}(K) = \sum_{i \in \mathcal{Y}} K_{ii}
$$

$$
\text{Var}(|Y|) = \sum_{i \in \mathcal{Y}} \lambda_i (1 - \lambda_i)
$$

Two examples of DPP:

- **Bernoulli Point Process**: $Y_i$ are independent following some Bernoulli distribution with parameter $p_i$. This is a DPP for the diagonal kernel $K = \text{diag}(p_1, \ldots, p_N)$.

- **Projection DPP**: $\forall i \in \mathcal{Y}, \lambda_i = 0 \text{ or } 1$.

Notice that for projection DPP the cardinality $|Y|$ is fixed: $|Y| = \sum_i \lambda_i$. 
Properties of DPP

**Cardinality**: it satisfies \( |Y| \sim \sum_{i \in Y} \text{Ber}(\lambda_i) \)

(sum of independent Bernoulli random variables of parameter \( \lambda_i \)). Hence

\[
\mathbb{E}(|Y|) = \sum_{i \in Y} \lambda_i = \text{Tr}(K) = \sum_{i \in Y} K_{ii}
\]

\[
\text{Var}(|Y|) = \sum_{i \in Y} \lambda_i (1 - \lambda_i)
\]

Two examples of DPP :

▶ Bernoulli Point Process :

\( Y_i \) are independent following some Bernoulli distribution with parameter \( p_i \). This is a DPP for the diagonal kernel \( K = \text{diag}(p_1, \ldots, p_N) \).

▶ Projection DPP :

\( \forall i \in \mathcal{Y}, \quad \lambda_i = 0 \text{ or } 1. \)

Notice that for projection DPP the cardinality \( |Y| \) is fixed : \( |Y| = \sum_i \lambda_i \).

**Exact sampling algorithm** using the spectral decomposition of \( K \)
(Hough-Krishnapur-Peres-Virág)
Motivation

Take advantage of the repulsive nature of DPP to:

- Sample subsets of well-spread pixels in image domain and use them for texture modeling based on shot noise.
- Subsample the set of patches of an image to efficiently summarize the diversity of the patches.
Outline

I. Determinantal point processes on pixels

II. Shot noise models driven by Determinantal Pixel Processes

III. Identifiability and Inference for Determinantal Pixel Processes

IV. Subsampling image patches using Determinantal Point Processes
Determinantal pixel processes (DPixP)

Framework for images:
Image domain: a discrete grid $\Omega$ of size $N_1 \times N_2$, then $N = N_1 N_2$ is the total number of pixels.

We consider a DPP $Y$ defined on $\Omega$, with kernel $K$, a matrix of size $N \times N$.

Hypothesis: $Y$ is stationary (with periodic boundary conditions)
Determinantal pixel processes (DPixP)

Framework for images:
Image domain: a discrete grid $\Omega$ of size $N_1 \times N_2$, then $N = N_1 N_2$ is the total number of pixels.

We consider a DPP $Y$ defined on $\Omega$, with kernel $K$, a matrix of size $N \times N$.

Hypothesis: $Y$ is stationary (with periodic boundary conditions)
- $K$ is a block-circulant matrix with circulant blocks: There exists a function $C : \Omega \rightarrow \mathbb{C}$ s.t.
  $$\forall x, y \in \Omega, \quad K_{xy} = C(x - y).$$
- $K$ is diagonalized in the 2D Discrete Fourier transform and the eigenvalues of $K$ are the Fourier coefficients of $C$.

Kernel function $C$

Fourier coefficients $\hat{C}$

A sample
The 2D discrete Fourier transform

Let \( f : \Omega \rightarrow \mathbb{C} \) be a function defined on \( \Omega = \{0, \ldots, N_1 - 1\} \times \{0, \ldots, N_2 - 1\} \). Its discrete Fourier transform \( \hat{f} \) is the function defined on \( \Omega \) by

\[
\forall \xi \in \Omega, \quad \hat{f}(\xi) = \sum_{x \in \Omega} f(x) e^{-2i\pi \langle x, \xi \rangle},
\]

where for \( x = (x_1, x_2) \in \Omega \) and \( \xi = (\xi_1, \xi_2) \in \Omega \), we denote the scalar product

\[
\langle x, \xi \rangle = \frac{x_1 \xi_1}{N_1} + \frac{x_2 \xi_2}{N_2}.
\]
The 2D discrete Fourier transform

Let \( f : \Omega \rightarrow \mathbb{C} \) be a function defined on \( \Omega = \{0, \ldots, N_1 - 1\} \times \{0, \ldots, N_2 - 1\} \). Its discrete Fourier transform \( \hat{f} \) is the function defined on \( \Omega \) by

\[
\forall \xi \in \Omega, \quad \hat{f}(\xi) = \sum_{x \in \Omega} f(x) e^{-2i\pi \langle x, \xi \rangle},
\]

where for \( x = (x_1, x_2) \in \Omega \) and \( \xi = (\xi_1, \xi_2) \in \Omega \), we denote the scalar product

\[
\langle x, \xi \rangle = \frac{x_1 \xi_1}{N_1} + \frac{x_2 \xi_2}{N_2}.
\]

1. **Inversion**: we can recover \( f \) from \( \hat{f} \), by the inverse discrete Fourier transform

\[
\forall x \in \Omega, \quad f(x) = \frac{1}{|\Omega|} \sum_{\xi \in \Omega} \hat{f}(\xi) e^{2i\pi \langle x, \xi \rangle}.
\]

2. **Parseval Theorem**:

\[
\|f\|_2^2 = \sum_{x \in \Omega} |f(x)|^2 = \frac{1}{|\Omega|} \sum_{\xi \in \Omega} |\hat{f}(\xi)|^2 = \frac{1}{|\Omega|} \|\hat{f}\|_2^2.
\]

3. **Convolution/Product**: The (periodic) convolution being defined by

\[
\forall x \in \Omega, \quad f \ast g(x) = \sum_{y \in \Omega} f(y) g(x - y), \quad \text{then} \quad \forall \xi \in \Omega, \quad \hat{f} \ast \hat{g}(\xi) = \hat{f}(\xi) \hat{g}(\xi).
\]
Determinantal pixel processes (DPixP)

Definition

Let \( C : \Omega \to \mathbb{C} \) be a function defined on \( \Omega \) such that

\[
\forall \xi \in \Omega, \quad \widehat{C}(\xi) \text{ is real and } 0 \leq \widehat{C}(\xi) \leq 1.
\]

Such a function will be called an admissible kernel. A random set \( X \subset \Omega \) is called a determinantal pixel process (DPixP) with kernel \( C \), if

\[
\forall A \subset \Omega, \quad \mathbb{P}(A \subset X) = \det(K_A),
\]

with \( K_A \) the matrix of size \( |A| \times |A| \) s.t. \( K_A = (C(x - y))_{x,y \in A} \).
Properties of DPixP

Cardinality: $|X| \sim \sum_{\xi \in \Omega} \text{Ber}(\hat{C}(\xi))$ and in particular

$$\mathbb{E}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi) = |\Omega|C(0) \quad \text{and} \quad \text{Var}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi)(1 - \hat{C}(\xi))$$
Properties of DPixP

**Cardinality:** \(|X| \sim \sum_{\xi \in \Omega} \text{Ber}(\hat{C}(\xi))\) and in particular

\[
\mathbb{E}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi) = |\Omega|C(0) \quad \text{and} \quad \text{Var}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi)(1 - \hat{C}(\xi))
\]

**Two examples:**

1. **Bernoulli Process:**

   \(C(0) = p\) and \(C(x) = 0, \ \forall x \in \Omega \setminus \{0\}\)

   \(\Leftrightarrow \forall \xi \in \Omega, \hat{C}(\xi) = p.\)

2. **Projection DPixP:**

   \(\forall \xi \in \Omega, \hat{C}(\xi)(1 - \hat{C}(\xi)) = 0.\)
Remark: Bernoulli point processes have the property of being the processes such that \( \text{Var}(|X|) \) is maximal among all DPixP with same \( \mathbb{E}(|X|) \).

Indeed, let \( p \in [0, 1] \) and let \( C \) be any admissible kernel such that 
\[
\mathbb{E}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi) = p|\Omega|.
\]
Then, by Cauchy-Schwarz inequality,
\[
\text{Var}(|X|) = \sum_{\xi \in \Omega} \hat{C}(\xi) - \sum_{\xi \in \Omega} \hat{C}(\xi)^2 = p|\Omega| - \sum_{\xi \in \Omega} \hat{C}(\xi)^2 
\leq p|\Omega| - \frac{1}{|\Omega|} \left( \sum_{\xi \in \Omega} \hat{C}(\xi) \right)^2 = p(1 - p)|\Omega|.
\]
And the equality holds when all \( \hat{C}(\xi) \) are equal to \( p \), i.e. \( C = p\delta_0 \).
Sequential simulation of a DPixP

Let us denote, for $\xi \in \Omega$, the function $\varphi_\xi$ defined on $\Omega$ by

$$\forall x \in \Omega, \quad \varphi_\xi(x) = \frac{1}{\sqrt{MN}} e^{2i\pi \langle x, \xi \rangle}.$$ 

Then $\{\varphi_\xi\}_{\xi \in \Omega}$ is an orthonormal basis of $L^2(\Omega; \mathbb{C})$.

Algorithm: Sequential simulation of a DPixP

1. Sample a random field $U = (U_\xi)_{\xi \in \Omega}$ where the $U_\xi$ are i.i.d. uniform on $[0, 1]$.
2. Define the “active frequencies” $\{\xi_1, \ldots, \xi_n\} = \{\xi \in \Omega; U(\xi) \leq \hat{C}(\xi)\}$, and denote,

$$\forall x \in \Omega, \quad v(x) = (\varphi_{\xi_1}(x), \ldots, \varphi_{\xi_n}(x)) \in \mathbb{C}^n.$$

3. For $k = 1$ to $n$ do:
   - Sample $X_1$ uniform on $\Omega$, and define $e_1 = v(X_1)/\|v(X_1)\|$.
   - For $k = 2$ to $n$, sample $X_k$ from the probability density $p_k$ on $\Omega$, defined by

$$\forall x \in \Omega, \quad p_k(x) = \frac{1}{n-k+1} \left( \frac{n}{MN} - \sum_{j=1}^{k-1} |e_j^* v(x)|^2 \right)$$

   - Define $e_k = w_k/\|w_k\|$ where $w_k = v(X_k) - \sum_{j=1}^{k-1} e_j^* v(X_k)e_j$.
4. Return $X = (X_1, \ldots, X_n)$.

DPixP and hard-core repulsion

Can we impose a minimal distance between points of a DPixP? What are the consequences on the kernel $C$?

Proposition

Let us consider $X \sim \text{DPixP}(C)$ on $\Omega$ and $e \in \Omega$. Then the following propositions are equivalent:

1. For all $x \in \Omega$, the probability that $x$ and $x + e$ belong simultaneously to $X$ is zero.

2. For all $x \in \Omega$, the probability that $x$ and $x + \lambda e$ belong simultaneously to $X$ is zero for $\lambda \in \mathbb{Q}$ such that $\lambda e \in \Omega$.

3. There exists $\theta \in \mathbb{R}$ such that the only frequencies $\xi \in \Omega$ such that $\hat{C}(\xi)$ is nonzero are located on the discrete line defined by $\langle e, \xi \rangle = \theta$.

4. $X$ contains almost surely at most one point on every discrete line of direction $e$.

This is called directional repulsion.
DPixP and hard-core repulsion

Example: Horizontal repulsion

\[ \hat{C} \]

Real part of \( C \)

Density during sampling

Realization

Conclusion on hard-core repulsion: The only DPixP imposing a minimum distance between the points is the degenerate DPixP made of a single pixel.
DPixP and hard-core repulsion

**Example**: Horizontal repulsion

- $\hat{C}$
- Real part of $C$
- Density during sampling
- Realization

**Conclusion on hard-core repulsion**: The only DPixP imposing a minimum distance between the points is the degenerate DPixP made of a single pixel.
Shot noise and texture modeling

The **spot noise** was introduced by J. van Wijk (*Computer Graphics*, 1991) for texture synthesis. Using a Poisson points process \( \{ x_i \} \subset \mathbb{R}^2 \), it has the form

\[
\forall x \in \mathbb{R}^2, \quad S(x) = \sum_i \beta_i g(x - x_i).
\]

Definition : Shot noise driven by a DPixP
Let $C$ be an admissible kernel, and let $g$ be a function defined on $\Omega$. Then, the shot noise random field $S$ driven by the DPixP of kernel $C$ and the spot $g$ is defined by

$$\forall x \in \Omega, \quad S(x) = \sum_{x_i \in X} g(x - x_i),$$

where $X = \{x_i\}$ is a DPixP of kernel $C$. 

Shot noise driven by a DPixP

Definition : Shot noise driven by a DPixP

Let $C$ be an admissible kernel, and let $g$ be a function defined on $\Omega$. Then, the shot noise random field $S$ driven by the DPixP of kernel $C$ and the spot $g$ is defined by

$$\forall x \in \Omega, \quad S(x) = \sum_{x_i \in X} g(x - x_i),$$

where $X = \{x_i\}$ is a DPixP of kernel $C$.

To compute the moments (mean, variance, kurtosis, etc.) of $S$, we first need to have a “Mecke-Campbell-Slivnyak” type formula in the DPixP framework.

Proposition : Moments formula

Let $X$ be a DPixP of kernel $C$, let $k \geq 1$ be an integer, and let $f$ be a function defined on $\Omega^k$. Then

$$\mathbb{E} \left[ \sum_{\substack{x_1, \ldots, x_k \in X \neq \emptyset}} f(x_1, \ldots, x_k) \right] = \sum_{y_1, \ldots, y_k \in \Omega} f(y_1, \ldots, y_k) \det(C(y_i - y_j)_{1 \leq i, j \leq k})$$
Shot noise driven by a DPixP : Moments

1. Mean value :

\[ \mathbb{E}(S(0)) = C(0) \sum_{y \in \Omega} g(y) = C(0) \hat{g}(0). \]

2. Covariance : (assume \( \hat{g}(0) = 0 \))

\[ \forall x \in \Omega, \quad \Gamma_S(x) := \text{Cov}(S(0), S(x)) = C(0) g \ast g_-(x) - (g \ast g_- \ast |C|^2)(x), \]

where \( g_-(x) := g(-x) \). And therefore

\[ \text{Var}(S(0)) = C(0) \sum_{y \in \Omega} g(y)^2 - (g \ast g_- \ast |C|^2)(0) \]

and

\[ \widehat{\Gamma}_S(\xi) = |\hat{g}(\xi)|^2 (C(0) - |\hat{C}|^2(\xi)). \]

The variance depends on the spot \( g \) and the DPP kernel \( C \) in a non trivial way.
Shot noise driven by a DPixP

\[
\text{Var}(S(0)) = C(0) \sum_{y \in \Omega} g(y)^2 - (g * g - * |C|^2)(0)
\]

\[
= \frac{n}{|\Omega|^2} \sum_{\xi \in \Omega} |\hat{g}(\xi)|^2 - \frac{1}{|\Omega|^2} \sum_{\xi, \xi' \in \Omega} |\hat{g}(\xi - \xi')|^2 \hat{C}(\xi) \hat{C}(\xi').
\]

Proposition: Shot noise with extreme variance

Consider a spot function \( g : \Omega \to \mathbb{R}^+ \) and \( n \in \mathbb{N} \) an expected cardinality for the DPixP.

**Maximal variance**: The DPixP with expected cardinality \( n \) associated with the spot \( g \) reaching maximal variance is the **Bernoulli process**.

**Minimal variance**: The DPixP with expected cardinality \( n \) associated with the spot \( g \) reaching minimal variance is the **projection DPixP** of \( n \) points, such that the \( n \) frequencies \( \{\xi_1, \ldots, \xi_n\} \) associated with the non-zero Fourier coefficients are localized to maximize

\[
\sum_{\xi, \xi' \in \{\xi_1, \ldots, \xi_n\}} |\hat{g}(\xi' - \xi')|^2.
\]

To approximate the maximization of the quadratic functional we use a simple greedy algorithm.

Inference for DPixP

**Inference**: We look for a kernel $C$ that would correspond to one (or several) realizations of a subset of pixels.

A given realization → ?

Which is the corresponding DPixP($C$)?
Inference for DPixP

**Inference**: We look for a kernel $C$ that would correspond to one (or several) realizations of a subset of pixels.

![A given realization](image1.png)

![Which is the corresponding DPixP($C$)](image2.png)

**Identifiability of the problem**: What is the equivalence class of a given kernel $C$?
Inference for DPixP - Identifiability

Proposition

Let $C_1$, $C_2$ be two kernels defined on $\Omega$, satisfying some reasonable hypotheses\(^1\).

Then, $\text{DPixP}(C_1) = \text{DPixP}(C_2)$ if and only if the Fourier coefficients of $C_2$ are translated and/or symmetric with respect to $(0, 0)$ from the Fourier coefficients of $C_1$.

Three DPixP kernels belonging the same equivalence class: they parameterize the same DPixP.

---

Inference for DPixP

- **Input**: $J$ realizations, $Y_1, \ldots, Y_J$, from the same DPiXP with unknown $C$ kernel.

- **Empirical estimator of the cardinality** $n = \frac{1}{J}(|Y_1| + \cdots + |Y_J|)$

- Let us consider the conditional distribution

$$p_C(x) = \begin{cases} 
\mathbb{P}(x \in X \mid 0 \in X) = C(0) - \frac{|C(x)|^2}{C(0)} & \text{if } x \neq 0, \\
0 & \text{if } x = 0.
\end{cases}$$

- Using **stationarity** an empirical estimator of $p_C$ is

$$\theta_J(x) = \begin{cases} 
\frac{1}{nJ} \sum_{i=1}^{J} \sum_{y \in \Omega} 1_{Y_i}(y)1_{Y_i}(y + x) & \text{if } x \neq 0, \\
0 & \text{if } x = 0.
\end{cases}$$
Inference for DPixP

- **Input**: $J$ realizations, $Y_1, \ldots, Y_J$, from the same DPiXP with unknown $C$ kernel.

- **Empirical estimator of the cardinality** $n = \frac{1}{J}(|Y_1| + \cdots + |Y_J|)$

- Let us consider the conditional distribution

  $$p_C(x) = \begin{cases} 
  \mathbb{P}(x \in X | 0 \in X) = C(0) - \frac{|C(x)|^2}{C(0)} & \text{if } x \neq 0, \\
  0 & \text{if } x = 0.
  \end{cases}$$

- Using **stationarity** an empirical estimator of $p_C$ is

  $$\theta_J(x) = \begin{cases} 
  \frac{1}{nJ} \sum_{i=1}^J \sum_{y \in \Omega} 1_{Y_i}(y) 1_{Y_i}(y + x) & \text{if } x \neq 0, \\
  0 & \text{if } x = 0.
  \end{cases}$$

- We propose to solve $\min_C \|p_C - \theta_J\|_2^2$ under the set of admissible kernels with expected cardinality $n$ using projected gradient descent.

- Convex constraint but highly non convex functional, a careful initialization is important (heuristic).

Conclusion: Satisfying results for projection DPixP, using a fast estimation algorithm.
Subsampling image patches using DPP

DPPs are widely used in statistics and in machine learning for selecting diverse subsets of points: k-means initialization, text summary (Kulesza-Taskar, Dupuy-Bach ...,), feature selections (Belhadji-Bardenet-Chainais), etc.

Patches of an image are seen as points in patch space $\mathbb{R}^{\omega^2}$.

**Question**: What is the best kernel $K$ to subsample image patches?

---

Discrete DPPs and $L$-ensembles

- Back to the general discrete setting with $\mathcal{Y} = \{1, \ldots, N\}$ and a matrix $K$ to determine $Y \sim \text{DPP}(K)$.
- $K$ is Hermitian and has its eigenvalues in the interval $[0, 1]$.
- If 1 is not an eigenvalue of $K$, one sets $L = K(I - K)^{-1}$ and one has the marginal probability

$$\forall A \subset \mathcal{Y}, \quad \mathbb{P}(Y = A) = \frac{\det(L_A)}{\det(I + L)}.$$

- Conversely, given any Hermitian matrix $L \succeq 0$ defines a DPP by setting $K = L(L + I)^{-1}$ the spectrum of which is within $[0, 1)$. This is called an $L$-ensemble.

- An $L$-ensemble kernel $L$ is easier to manipulate for parametric modeling (e.g. rescale by multiplying by any constant etc.). $K$ and $L$ share the same eigenvectors.
Subsampling image patches using DPP

We define on the set of patches $\mathcal{P} = \{p_i, 1 \leq i \leq N\}$ an admissible matrix $K$ or an $L$-ensemble kernel $L$ to define $K = L(L + I)^{-1}$.

We consider several examples of kernels:

- **Gaussian kernel based on the intensity of the patches:**
  
  $$L_{ij} = \exp \left( -\frac{||p_i - p_j||_2^2}{s^2} \right)$$

  The parameter $s$ is fixed as the median of the distances of intensities between the patches.

- **Gaussian kernel based on the $k$ first PCA components of patches:**
  
  $$L_{ij} = \exp \left( -\frac{||PCA_i - PCA_j||_2^2}{s^2} \right)$$

- **Kernel based on a quality/diversity decomposition, where**
  
  $q_i \in \mathbb{R}^+, \phi_i \in \mathbb{R}^D$, s.t. $||\phi_i||_2 = 1$, $L_{ij} = q_i \phi_i^T \phi_j q_j$

- **Projection kernel $K$ obtained in maximizing a reconstruction evaluation**
  
  $$\mathbb{E} \left( \sum_{p_i \in \mathcal{P}} \sum_{Q \in \mathcal{Q}} 1_{||p_i - Q||_2 \leq \alpha} \right)$$, where $Q \sim \text{DPP}(K)$. 

Subsampling image patches using DPP

Reconstruction of an image from patches sampled by DPP:
Each patch in the image is replaced by its closest representative in the subset $Y \sim \text{DPP}(K)$ (nearest neighbor for the $\ell_2$-distance).
Comparison of the different kernels for patch subsampling

**Expected cardinality of the DPP : 5 patches.**
Each patch in the image is replaced by its closest representative in the subset $Y \sim \text{DPP}(K)$ (nearest neighbor for the $\ell_2$-distance).

Comparison of the different kernels for patch subsampling

Reconstruction errors for the previous image VS. expected cardinality

- \( \{ p_i, 1 \leq i \leq N \} \), patches of the image
- \( Q \sim \text{DPP}(K) \), subset of patches sampled using the given DPP

\[
E_1 = \frac{1}{N} \sum_{i=1}^{N} d(p_i, Q)^2
\]
\[
E_2 = \max_{i \in \{1, \ldots, N\}} d(p_i, Q)^2
\]
\[
\text{PSNR}
\]

Conclusion:

- Uniform sampling lags always behind.
- Qual/div and optimized kernels are not competitive and limited in cardinal by construction.
- Intensity and PCA kernels are the best choice for every measurements.
Conclusion and perspectives

- (Fast) sampling algorithms for DPPs?
- Many questions for texture modeling: from an image, estimate the spot function and the kernel of the DPP?
- Selecting the «best» kernel for representing the patches of an image depending on the final task (compression, denoising, texture synthesis, etc.).
- Geometry of the shot noise driven by a DPP?
Conclusion and perspectives

Spectral sampling algorithm

**Exact sampling algorithm** using spectral decomposition of $K$
(Hough-Krishnapur-Peres-Virág)

- Eigendecomposition $(\lambda_j, v^j)$ of the matrix $K$.
- Select active frequencies: Sample a Bernoulli process $X \in \{0, 1\}^N$ with parameter $(\lambda_j)_j$.
  Denote $n$ the number of active frequencies, $\{X = 1\} = \{j_1, \ldots, j_n\}$.
  and the matrix $V = (v^{j_1} v^{j_2} \cdots v^{j_n}) \in \mathbb{R}^{N \times n}$ with $V_k \in \mathbb{R}^n$ the $k$-th row of $V$, for $k \in \mathcal{Y}$.
- Output the sequence $Y = \{y_1, y_2, \ldots, y_n\}$ sequentionaly sampled as follows:
  For $l = 1$ to $n$:
    - Draw a point $y_l \in \mathcal{Y}$ from the probability distribution
      $$p^l_k = \frac{1}{n - l + 1} \left( \|V_k\|^2 - \sum_{m=1}^{l-1} |\langle V_k, e_m \rangle|^2 \right), \forall k \in \mathcal{Y}.$$  
    - If $l < n$, define $e_l = \frac{w_l}{\|w_l\|} \in \mathbb{R}^n$ where $w_l = V_{y_l} - \sum_{m=1}^{l-1} \langle V_{y_l}, e_m \rangle e_m$.

Shot noise driven by a DPixP: Limit theorems

- **Law of large numbers** and **central limit theorem** exist for shot noise based on DPixP.

- One needs to use increasing-domain asymptotics: Expand the DPP to $\mathbb{Z}^2$ and let the support of the kernel grow:\n
\[ S_M(y) = \frac{1}{M^2} \sum_{x \in \mathcal{X}} g(y - \frac{x}{M}). \]

(a) Spot (b) $S_M, M = 1$ (c) $S_M, M = 2$

(d) $S_M, M = 3$ (e) $S_M, M = 6$ (f) $\mathcal{N}(0, \Sigma(C))$

---

Shot noise driven by a DPixP : Limit theorems

For limit theorems, one needs to use increasing-domain asymptotics: Expand the DPP to $\mathbb{Z}^2$ and let the support of the kernel grow $^4$.

Proposition

Let $g$ be a continuous function on $\mathbb{R}^2$ with compact support, $X \sim \text{DPixP}(C)$ and $S_M$ the shot noise: $S_M(y) = \frac{1}{M^2} \sum_{x \in X} g \left( y - \frac{x}{M} \right)$, $\forall y \in \mathbb{Z}^2$. Then,

$$S_M(0) = \frac{1}{M^2} \sum_{x \in X} g \left( -\frac{x}{M} \right) \xrightarrow{M \to \infty} C(0) \int_{\mathbb{R}^2} g(x)dx, \text{ a.s and in } L^1. \tag{1}$$

If $g$ has zero mean, $\forall x_1, \ldots, x_m \in \mathbb{Z}^2$,

$$\sqrt{M^2} \left( S_M(x_1), \ldots, S_M(x_m) \right) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \Sigma(C)) \quad \text{with, for all } k, l \in \{1, \ldots, m\}, \tag{2}$$

$$\Sigma(C)(k, l) = \left( C(0) - \|C\|_2^2 \right) R_g(x_l - x_k).$$

where $R_g$ is the autocorrelation of $g$.

---

Inference for DPixP - Identifiability

Proposition
Let $C_1, C_2$ be two kernels defined on $\Omega$, satisfying some *reasonable hypotheses*\(^1\) with associated matrices $K_1$ and $K_2$ s.t. $K_1$ is irreducible. If $N \geq 4$, we suppose also that, for all partition of $\mathcal{Y}$ in two subsets $\alpha, \beta$, $|\alpha| \geq 2, |\beta| \geq 2$, $\text{rank}(K_1)_{\alpha \times \beta} \geq 2$.

Then, $\text{DPixP}(C_1) = \text{DPixP}(C_2)$ if and only if the Fourier coefficients of $C_2$ are translated and/or symmetric with respect to $(0, 0)$ from the Fourier coefficients of $C_1$ that is

$$\text{DPixP}(C_1) = \text{DPixP}(C_2) \iff \exists \tau \in \Omega \text{ s.t. either } \forall \xi \in \Omega, \widehat{C}_2(\xi) = \widehat{C}_1(\xi - \tau)$$

$$\text{ou } \forall \xi \in \Omega, \widehat{C}_2(\xi) = \widehat{C}_1(-\xi - \tau).$$

Two cases if $K_1$ do not satisfy the hypotheses:

- $K_1$ is irreducible but there exists a partition $(\alpha, \beta)$ s. t. the $\text{rank}(K_1)_{\alpha \times \beta} = 1$.

- $K_1$ is similar by permutation of a block diagonal matrix with similar blocks: This is a degenerate case e.g. with intermixed independent copies of the same DPP on a smaller grid.
Generate a texture image visually similar to an input texture image

Strategy:

1. Generate a Gaussian random field \( U \) with the same mean and covariance as the input texture.
2. Define an optimal transport map \( T \) to correct the Gaussian patch distribution from the empirical patch distribution of the original texture.
3. Use \( T \) to correct the local features of the Gaussian image \( U \).

---

Synthesis time is highly dependent on the size of the patch distribution.

Initial strategy: uniform selection of 1000 patches.

**Contribution**

Subsampling of the patch space using a DPP to better represent the patch set.

Proposition: Select only 100 or 200 patches thanks to a DPP of kernel $K = L(L + I)^{-1}$ with

$$\forall i, j \in \{1, \ldots, I\}, \quad L_{ij} = \exp \left( -\frac{||p_i - p_j||_2^2}{s^2} \right)$$

Acceleration of a texture synthesis by example algorithm

- Selection of a subset of patches with the DPP
  \[ Q = \{ q_j, 1 \leq j \leq J \} \sim \text{DPP}(K). \]

- Estimation of the summarized patch distribution
  \[ \nu^* = \sum_{j=1}^{J} \nu_j^* \delta_{q_j} \]

  with weights \( \nu_j^* \) obtained by minimizing the Wasserstein distance between \( \nu \) and the empirical distribution of all the patches.

- DPP simulation: Done only once during the estimation of the transport map \( T \).

**Acceleration**: To synthesize an image of size \( 1024 \times 1024 \):

- Original algorithm: 1000 patches. Time: 1.7”.
- Proposed DPP-based strategy:

<table>
<thead>
<tr>
<th>Nb of patches</th>
<th>50</th>
<th>100</th>
<th>200</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>0.19”</td>
